## Remarks/Arguments

Reconsideration of the above-identified application in view of the present amendment is respectfully requested. Attached herewith is a declaration under 37 CFR 1.132 from Dr. Mary Laughlin, an inventor of the subject application. Below is a discussion of the 35 U.S.C. §103(a) rejection of claims 1, 2, 4, 10-12, 21, 23-36, 40-43, 50-54, 56, 57, and 62-69.

Claims 1, 2, 4, 10-12, 21, 23-36, 40-43, 50-54, 56, 57, and 62-69 remain rejected under 35 U.S.C. §103(a) as being unpatentable over Strauer et al. (2002, Circulation 106: 1913-1918) in view of Shake et al. (2002, Annals of Thoracic Surgery 73: 1919-1926), Ueno et al. (U.S. Patent Application Publication No. 2002/0037278), Kawamoto et al. (2001, Circulation 103: 634-637; reference CJJ on 11/13/06 IDS), Itescu (2003, U.S. Patent Application Publication No. 2003/0199464), and Peichev et al. (2000, Blood 95: 952-958; reference CZZZ on 4/26/06 IDS).

Applicants respectfully submit that claims 1 and 57 are patentable over Strauer et al. in view of Shake et al., Ueno et al., Kawamoto et al., Itescu et al., and Peichev et al. because: (1) the combination of Strauer et al., Shake et al., Ueno et al., Kawamoto et al., Itescu et al., and Peichev et al. does not teach or suggest all the limitations of claim 1 and 57; (2) the Office Action has failed to provide a reasonable rationale to combine Strauer et al., Shake et al., Ueno et al., Kawamoto et al., Itescu et al., and Peichev et al. to teach administering to a subject a therapeutically effective amount of a first enriched population of cells comprising at least 75% human CD133+/CD34+ endothelial progenitor cells enriched from umbilical cord blood and a second enriched population of cells consisting essentially

of human mesenchymal stem cells; (3) one of ordinary skill in art would not find it predictable and/or have a reasonable expectation of success in view of Strauer et al., Shake et al., Ueno et al., Kawamoto et al., Itescu et al., and Peichev et al. to treat ischemic tissue or induce formation of blood vessels in ischemic tissue by administering to a subject a therapeutically effective amount of a first enriched population of cells comprising at least 75% human CD133+/CD34+ endothelial progenitor cells enriched from umbilical cord blood and a second enriched population of cells consisting essentially of human mesenchymal stem cells; and (4) the invention recited in claims 1 and 57 exhibits unexpected results.

 The combination of Strauer et al., Shake et al., Ueno et al., Kawamoto et al., Itescu et al., and Peichev et al. does not teach or suggest to one of ordinary skill in the art all the limitations of claims 1 and 57.

It is well settled, that to establish a prima facie case of obviousness of a claimed invention, all claim limitations must be taught or suggested by the prior art. 

In re Royka, 490 F.2d 981, 180 USPO 580 (CCPA 1974). Strauer et al. in combination with Shake et al., Ueno et al., Kawamoto et al., Itescu et al., and Peichev et al. do not teach or suggest to one of ordinary skill in the art administering to a subject a therapeutically effective amount of a first enriched population of cells comprising at least 75% human CD133+/CD34+ endothelial progenitor cells enriched from umbilical cord blood.

As discussed in the Office Action, Strauer *et al.* teach isolating bone marrow (BM) from human, isolating mononuclear bone marrow cells (BMCs) therefrom, cultivating them overnight, and administering over 10<sup>6</sup> monuclear BMCs to the ischemic tissue using a balloon catheter. Strauer *et al.* also teach that 0.65% of the

isolated mononuclear BMCs are AC133+ and that the BMCs include mesenchymal stem cells. As further discussed in the Office Action, Strauer *et al.* do not teach or suggest administering to a subject a therapeutically effective amount of a first enriched population of cells comprising at least 75% human CD133+/CD34+ endothelial progenitor cells enriched from umbilical cord blood.

Shake et al., Ueno et al., Kawamoto et al., Itescu et al., and Peichev et al. do not overcome the deficiencies of the Strauer et al. and specifically do not teach administering to a subject a therapeutically effective amount of a first enriched population of cells comprising at least 75% human CD133+/CD34+ endothelial progenitor cells enriched from umbilical cord blood.

Shake et al. teach isolating MSCs from bone marrow and culturing them such that hematopoietic cells, fibroblasts, and non-MSC adherent cells are washed away, yielding a purified MSC culture. Shake et al., however, do not teach that an enriched population of cells consisting essentially of MSCs can be administered in combination with another enriched population of cells let alone an enriched population of cells comprising 75% human CD133+/CD34+ endothelial progenitor cells enriched form umbilical cord blood.

Ueno et al. teach methods of treating ischemic tissues by administering bone marrow mononuclear cells. Ueno et al., however, do not teach or suggest administering to a subject a therapeutically effective amount of a first enriched population of cells comprising at least 75% human CD133+/CD34+ endothelial progenitor cells enriched from umbilical cord blood. A population of BMCs, which as noted in Strauer et al., comprising 0.65% endothelial progenitor cells, is not a first

enriched population of cells comprising at least 75% human CD133\*/CD34\* endothelial progenitor cells enriched from umbilical cord blood.

Kawamoto *et al.*, as discussed in the Office Action, teach administering expanded endothelial progenitor cells (EPCs) to rats in which myocardial ischemia has been induced. The EPCs are selected for CD34<sup>+</sup> cells and therefore comprise an enriched population of CD34<sup>+</sup> cells. An enriched population of CD34<sup>+</sup> cells is not an enriched population of cells comprising of CD133<sup>+</sup> cells and therefore is not an enriched population comprising at least 75% human CD133<sup>+</sup>/CD34<sup>+</sup> endothelial progenitor cells enriched from umbilical cord blood.

Itsecu, as discussed in the Office Action, teaches methods of regeneration myocardial tissue after ischemic tissue by administering endothelial progenitor cells that can express CD117, CD34, AC133, or a high level of intracellular GATA activity. Itsecu teaches in the Examples from paragraphs 106+ that a population of CD34\* cells of 98% purity comprising 6-12% CD117<sup>bright</sup> cells can be administered to a subject. Itsecu, however, does not teach or suggest administering to a subject a therapeutically effective amount of a first enriched population of cells comprising at least 75% human CD133+/CD34+ endothelial progenitor cells enriched from umbilical cord blood. Itsecu teaches only that the mononuclear cells can be selected for CD34\* and that these selected and purified cells include at least some cells that include CD133\* markers. Itsecu does not teach selecting for CD133\* and CD34\* to achieve an enriched population of cells that include at least 75% human CD133\*/CD34\* endothelial progenitor cells enriched from umbilical cord blood.

Peichev et al. teach at page 953, first column, last paragraph to second column first paragraph.

"that a small subset of CD34+ cells derived from hematopoietic sources express AC133 and VEGFR-2...[and] that circulating CD34+ cells expressing VEGFR-2 and AC133 comprise a functional population of CEPs cells that may play a role in postnatal angiogenesis or vasculogenesis."

Peichev et al. also note on page 955, column 1, second paragraph, that:

"CD34" cells isolated from different hematopoietic sources were analyzed by 2-color flow cytometry using PE-conjugated MoAb to AC133 and FITC-conjugated MoAb to VEGFR-2. Almost all of the VEGFR-2+ cells derived from mobilized PB that expressed VEGFR-2 also coexpressed AC133 (Figure 2A). However, although mature early-passage HUVECs expressed VEGFR-2, they failed to express AC 133 (Figure 2B, 2C). These data suggest that CD34<sup>+</sup> cells coexpressing VEGFR-2 and AC133 may represent a phenotypically distinct population of CEPs. The frequency of CD34<sup>+</sup> cells expressing VEGFR-2 and AC133 in PB was only 0.4 ± 0.2% of the total CD34<sup>+</sup> population (0.002% of total mononuclear cells). However, with G-CSF mobilization there was an increase in the number of AC133+VEGFR-2+ CEPs to 2.0 + 0.5% of the CD34+ cells (0.02% of total mobilized mononuclear cells). CB- and FL-derived CD34<sup>+</sup> cells contained 1.4 + 0.5% and 1.2 ± 0.3% AC133+VEGFR-2\* cells, respectively. The number of AC133-CD34+VEGFR-2+ cells, which most likely represent mature circulating endothelial cells, composed a very small percentage of the circulating population in mobilized blood. These data demonstrate the existence of low levels but persistent numbers of circulating AC133\*VEGFR-2\* cells in various hematopoietic sites."

Peichev et al. further note on page 956:

"We have previously shown that surfaces of LVADs in contact with circulating blood are colonized with CD34\* cells with high proliferative capacity, giving rise to a biologically nonthrombogenic neo-intima. Close scrutiny of the LVAD surfaces shows that  $4\pm1\%$  of the mononuclear cells express AC133\* and VEGFR-2\* cells, suggesting that circulating CEPs have the capacity to colonize neo-intimal surfaces (Figure 6). The presence of AC133\*VEGFR-2\* cells detected on LVADs was more prominent in formed neo-intima explanted early after operation (28 days)."

Accordingly, Peichev et al. only teach that it is possible to isolate

CD34\*CD133\* cells and that CD34\*CD133\* cells in circulating blood have the
capacity to colonize neo-intimal surfaces. Peichev et al. do not teach administering

CD34\*CD133\* cells to a subject for any purpose let alone to treat ischemic tissue or
induce formation of blood vessels nor that an enriched population of CD34\*CD133\*

cells comprising at least 75% human CD133\*/CD34\* endothelial progenitor cells can
be administered to a subject and would have any potential effect on ischemic tissue
or neovascularization alone or in combination with a second population of
mesenchymal stem cells. The mere fact the Peichev et al. teach CD133\*CD34\* cells
can be isolated does not teach that such isolated cells can be administered to a
subject in a first enriched population of cells comprising at least 75% human

CD133\*CD34\* endothelial progenitor cells enriched from umbilical cord blood.

Accordingly, none of the references cited in the Office Action teach or suggest administering to a subject a therapeutically effective amount of a first enriched population of cells comprising at least 75% human CD133\*/CD34\* endothelial progenitor cells enriched from umbilical cord blood for any purpose let alone administering a first enriched population of cells comprising at least 75% human CD133\*/CD34\* endothelial progenitor cells enriched from umbilical cord blood to treat ischemic tissue or induce formation of blood vessels in ischemic tissue. The Office Action provides no teaching, suggestion, or motivation of how this limitation is met by the references or in the knowledge generally available to one of ordinary skill in the art

Moreover, even if the any of references suggested administering human CD133+/CD34+ endothelial progenitor cells enriched from umbilical cord blood, the Office Action has provided no teaching that one skilled in the art can or would select for an enriched population of CD133<sup>+</sup>/CD34<sup>+</sup> endothelial progenitor cells comprising the percentage recited in the claims, i.e., at least 75% human CD133+/CD34+ endothelial progenitor cells enriched from umbilical cord blood, or that one would administer such an enriched population to treat ischemic tissue in a subject. Nor do the references suggest that the percentage of CD133+/CD34+ endothelial progenitor cells in the first enriched population of cells is recognized as a result effective variable that can be optimized by routine experimentation. In order for a variable to be optimized it must first be recognized as a result effective variable (In re Antoine. 195 USPQ 7.9 (CCPA 1977)). There is no teaching or suggestion in any references cited by the Office Action that optimizing the percentage human CD133+/CD34+ endothelial progenitor cells in an enriched population of cells would have any effect when administered to ischemic tissue of a subject or that it is desirable to optimize the percentage of human CD133+/CD34+ endothelial progenitor cells in an enriched population of cells.

The Office Action also notes that the limitations to claims 1 and 57, which indicate the EPCs are enriched from umbilical cord blood, is a product by process limitation and that the burden shifts to Applicants to show that the manner in which the administered EPCs were isolated effects the EPCs' material properties.

Attached herewith is a declaration under 37 CFR 1.132 from Dr. Mary Laughlin, an inventor of the subject patent application. The declaration includes a publication from Dr. Laughlin entitled, "Umbilical cord blood-selected CD133+ cells exhibit vasculogenic functionality in vitro and in vivo" (Cytotherapy, 2010; 12: 67-78). The publication shows on pages 70+ that CD133\*/CD34\* cells isolated from umbilical cord blood and bone marrow display a different surface phenotype. The publication also compared the effectiveness of umbilical cord blood (UCB) derived CD133\* cells to BM CD133\* cells, non-selected bone marrow-derived mononuclear cells (BM MNCs), and non-selected UCB MNCs at mediating neovascularization in vivo in a non-obese diabetic/severe combined immunodeficiency disease (NOD/SCID) mouse femoral ligation vascular injury model. The publication found: (i) CD133<sup>+</sup> cells selected from UCB exhibited robust vasculogenic functionality compared with BM CD133+ cell, UCB MNCs, and BM MNCs in response to ischemia; (ii) blood flow in NOD/SCID mice 4 weeks after femoral ligation was significantly higher in animals injected with UCB-derived CD133\*-cells compared to BM CD133<sup>+</sup> cells, UCB MNCs, BM MNCs and control at 28 days despite administration of a lower cell dose (0.5 X 10<sup>6</sup> CD133<sup>+</sup> versus 1.0 X 10<sup>6</sup> MNC), highlighting the benefit of using a selected cell population instead of heterogeneous MNC; and (iii) examination of human cell engraftment in the marrow was highest in NOD/SCID mice receiving UCB-derived CD133+ cells compared to NOD/SCID receiving BM CD 133+ cells, UCB MNCs, and BM MNCs. Accordingly, CD133+ endothelial progenitor cells enriched from umbilical cord display a different phenotype than CD133+ cells enriched from bone marrow and when administered to a NOD/SCID mouse femoral ligation vascular injury model provided improved

vasculogenic functionality compared with BM CD133<sup>+</sup> cells and BM MNCs in response to ischemia.

Thus, CD133\*/CD34\* endothelial progenitor cells enriched from umbilical cord blood are different in kind and provide a different result when administered to ischemic tissue of a subject than CD133\*/CD34\* endothelial progenitor cells enriched from bone marrow, and the limitation of administering a first enriched population of cells comprising at least 75% human CD133\*/CD34\* endothelial progenitor cells enriched from umbilical cord blood to treat ischemic tissue or promote neovascularization alone or in combination with a second enriched population of cells consisting essentially of human mesenchymal stem cells is not taught by the combination of references noted in the Office Action.

ii. The Office Action has failed to provide a reasonable rationale to combine Strauer et al., Shake et al., Ueno et al., Kawamoto et al., Itescu et al., and Pelchev et al. to teach administering to a subject a therapeutically effective amount of a first enriched population of cells comprising at least 75% human CD133+/CD34+ endothelial progenitor cells enriched from umbilical cord blood and a second enriched population of cells consisting essentially of human mesenchymal stem cells.

To overcome the deficiency in the teachings of Strauer et al., Shake et al.,

Ueno et al., Kawamoto et al., Itescu et al., and Peichev et al. as to the administration

a first enriched population of cells comprising at least 75% human CD133\*/CD34+

endothelial progenitor cells enriched from umbilical cord blood to treat ischemic

tissue or induce formation of blood vessels, the Office Action concludes that:

"The skilled artisan would have been motivated to enrich the CD34+CD133+EPCs in the administered composition of Strauer et al. because Kawamoto et al. recognized that EPCs promote neovascularization of ischemic tissue; therefore, administering more cells known at the time of the invention to achieve the desired result of

Strauer et al. would improve the outcome of the method of Strauer et al." (Emphasis added)

Applicants fail to see the relevance of this statement as to why one skilled in the art would administer a first enriched population of cells comprising at least 75% human CD133\*/CD34\* endothelial progenitor cells to treat ischemic tissue or induce formation of blood vessels in ischemic tissue. Kawamato et al. only teaches administration of an expanded CD34<sup>+</sup> endothelial progenitor cells population to treat myocardial infarction. Kawamato et al. do not teach that is population is an enriched population of cells comprising at least 75% human CD133+/CD34+ endothelial progenitor cells enriched from umbilical cord blood. As discussed in Applicants' previous response with respect to Kocher et al., less than 24% of mononuclear cells selected for CD34+ cells express AC133. (% of CD34+ cells that are CD117+ x % of CD117<sup>dim</sup> and CD117<sup>bright</sup> cells that are VEGFR-2+). Strauer et al., as discussed above, only teach administering a heterogenous population of BMCs and do not teach administering an enriched population of cells comprising at least 75% human CD133+/CD34+ endothelial progenitor cells enriched from umbilical cord blood. Peichey et al., as further discussed above, teach only that CD133\*CD34\* cells can be isolated and do not teach that such isolated cells can be administered to a subject in an enriched population of cells comprising at least 75% human CD133+/CD34+ endothelial progenitor cells to treat ischemic tissue.

The fact that CD34\* cells can be used to treat a myocardial infarction provides no basis in reason or fact to one skilled in the art that an enriched population of population of cells comprising a selected population of at least 75% human CD133\*/CD34\* endothelial progenitor cells could be used to treat myocardial

infarction or "would improve the outcome of the method of Strauer et al." as suggested by the Office Action and as noted above. Nor has the Office Action provide an evidence in fact or technical literature to support the conclusory statement that that an enriched population of population of cells comprising at least 75% human CD133\*/CD34\* endothelial progenitor cells would improve the outcome of the method of Strauer et al.

The Supreme Court of the United States acknowledged that rejections on obviousness grounds cannot be sustained by mere conclusory statements, and that instead, there must be some rational underpinning to support the legal conclusion of obviousness. *KSR Int'l Co. v. Teleflex*, 82 USPQ2d 1385, 1396 (2007). In particular, to establish a *prima facie* case for obviousness, there must be "a reason that would have prompted a person of ordinary skill in the relevant field to combine the elements in the way the claimed new invention does." *Takeda Chemical Indus.*, *Ltd. v. Alphapharm Pty. Ltd.*, 492 F.3d 1350, 1356-57 (Fed. Cir. 2007) *quoting KSR Int'l Co. v. Teleflex*, 82 USPQ2d 1385, 1396 (2007). The Office Action has failed to provide a reasonable rationale as to why a skilled would administer an enriched population of population of cells comprising at least 75% human CD133\*/CD34\* endothelial progenitor cells enriched from umbilical cord blood to a subject.

Moreover, it has been held that a claimed composition would have not have been obvious where there was no reason to modify the closest prior art composition to obtain the claimed composition and the prior art taught that modifying the closest prior art would destroy its advantageous properties. *Eisai Co. Ltd. V. Dr. Reddy's Labs., Ltd.*, 533 F.3d 1353 (Fed Cir. 2008).

Here. Strauer et al., which was identified in the Office Action as the closest prior art, teach several different fractions of mononuclear BMCs may contribute to the regeneration of necrotic myocardium and vessels. In order to utilize this large and perhaps heterogeneous regenerative potential. Strauer et al. used all mononuclear cells from the bone marrow aspirate as a whole, rather than a subpopulation of EPCs (i.e., human CD133\*/CD34\* endothelial progenitor cells enriched from umbilical cord blood). As discussed above, the prior art cited by the Office Action provides no teaching that a subpopulation of EPCs comprising human CD133<sup>+</sup>/CD34<sup>+</sup> endothelial progenitor cells enriched from umbilical cord blood could be used for treating ischemic tissue in a subject or would be desirable to use compared to other subpopulations of EPCs as well as mixed populations of BMCs. Accordingly, there was no reason to modify Strauer et al. to use a subpopulation of EPCs comprising human CD133<sup>+</sup>/CD34<sup>+</sup> endothelial progenitor cells enriched from umbilical cord blood instead of using the mixed population of BMCs as taught by Strauer et al. Therefore, it would not be obvious to modify Strauer et al. to use a subpopulation of EPCs let alone an enriched population of population of cells comprising at least 75% human CD133\*/CD34\* endothelial progenitor cells enriched from umbilical cord blood.

Additionally, the Office Action fails to provide a reasonable rationale as to why a skilled artisan would administer a first enriched population of cells comprising at least 75% human CD133\*/CD34\* endothelial progenitor cells enriched from umbilical cord blood to treat ischemic tissue or induce formation of blood vessels in

combination with a second enriched population of cells consisting essentially of human mesenchymal stem cells.

## The Office Action states:

The person of ordinary skill in the art would have had a further reasonable expectation of success in coadministering the EPCs of Strauer et al. with the purified MSCs of Shake et al. because the cited references teach that both cells promote healing after myocardial infarction. "It is prima facie obvious to combine two compositions each of which is taught by the prior art to be useful for the same purpose, in order to form a third composition to be used for the very same purpose.... [The idea of combining them flows logically from their having been individually taught in the prior art." In re Kerkhoven, 626 F.2d 846, 850, 205 USPQ 1069,1072 (CCPA 1980) (citations omitted). See M.P.E.P. § 2144.06. Since Shake et al. teach that their MSCs are "purified" after their culturing step, the level of enrichment would have been a matter of routine optimization at the time of the invention, the skilled artisan recognizing that Shake et al. identified a property of MSCs (i.e., cardiac remodeling) and that it would have been desirable to administer as many cells with that property as possible in treating myocardial infarction."

The prior art relied on by Examiner including Strauer et al., Shake et al., Ueno et al., Kawamoto et al., Itescu et al., and Peichev et al., however, neither teaches nor suggests that an enriched population of cells comprising at least 75% human CD133\*/CD34\* endothelial progenitor cells enriched from umbilical cord blood is equivalent to (1) a CD34\* EPC population as taught in Kawamato et al., (2) a heterogenous population of mononuclear BMCs as taught in Strauer et al., or (3) an isolated MSC population as taught in Shake et al.

It has been held that an examiner's reliance on equivalents as a rationale supporting an obviousness rejection is inappropriate without evidence that the equivalency was recognized in the prior art. See In re Ruff, 256 F.2d 590, 599 (CCPA 1958) ("The equivalence must be disclosed in the prior art").

This analysis is consistent with KSR, which notes that:

[a]Ithough common sense directs one to look with care at a patent application that claims as innovation the combination of two known devices according to their established functions, it can be important to identify a reason that would have prompted a person of ordinary skill in the relevant field to combine the elements in the way the claimed new invention does.

KSR. 550 U.S. at 418. In the instant case, the method of Claim 1 is directed to administering an enriched population of cells comprising at least 75% human CD133\*/CD34\* endothelial progenitor cells not CD34\* EPCs or heterogenous mononuclear BMCs. There is no discussion in the prior art cited by the Examiner that an enriched population of cells comprising at least 75% human CD133+/CD34+ endothelial progenitor cells enriched from umbilical cord blood is equivalent to or has even has similar effects as an enriched CD34\* population or a heterogenous mononuclear BMC population in treating ischemic tissue or inducing formation of blood vessels. Moreover, the Examiner has not identified any reason which would have prompted the ordinary artisan to select an enriched population of cells comprising at least 75% human CD133+/CD34+ endothelial progenitor cells for treating ischemic tissue or promoting neovascularization in ischemic tissue. Accordingly, the Office Action has failed to provide a reasonable rationale as to why a skilled would administer to a subject an enriched population of population of cells comprising at least 75% human CD133+/CD34+ endothelial progenitor cells enriched from umbilical cord blood in combination with a second enriched population of cells consisting essentially of human mesenchymal stem cells.

One of ordinary skill in art would not find it predictable and/or have a reasonable expectation of success of treating ischemic tissue or inducing formation of blood vessels in ischemic tissue by administering to a subject a therapeutically effective amount of a first enriched population of cells comprising at least 75% human CD133"/CD34" endothelial progenitor cells enriched from umbilical cord blood and a second enriched population of cells consisting essentially of human mesenchymal stem cells.

In KSR, the Supreme Court stated that when an obvious modification "leads to the anticipated success," the invention is likely the product of ordinary skill and is obvious under 35 U.S.C. § 103, 127 S. Ct. at 1742. "[O]bviousness cannot be avoided simply by a showing of some degree of unpredictability in the art so long as there was a reasonable probability of success." Pfizer, 480 F.3d at 1364 (citing In re Corkill, 771 F2d 1496, 1500 (Fed. Cir. 1985)).

Cases following KSR, however, have found that obviousness is not found where the prior art [gives] either no indication of which parameters [are] critical or no direction as to which of many possible choices is likely to be successful" In re O'Farrell, 853 F.2d 894, 903 (Fed. Cir. 1988). In such cases, "courts should not succumb to hindsight claims of obviousness. "In re Kubin, 561 F.3d 1351, 1359 (Fed Cir. 2009). Similarly, patents are not barred just because it was obvious "to explore a new technology or general approach that seemed to be a promising field of experimentation, where the prior art gave only general guidance as to the particular form of the claimed invention or how to achieve it." In re O'Farrell, 853 F.2d at 903.

As discussed above, Strauer et al. give only general guidance to methods of treating to treating myocardial infarction using mononuclear BMCs and do not specifically teach treating ischemic tissue or inducing formation of blood vessels in a subject by administering an enriched population of population of cells comprising at least 75% human CD133\*/CD34\* endothelial progenitor cells in combination with a

second enriched population of cells consisting essentially of human mesenchymal stem cells.

Strauer et al. discuss at pages 1916-1917 that:

In recent years, several laboratories have shown that environmentally dictated changes of fate (transdetermination) are not restricted to stem cells but may also involve progenitor cells at different steps of a given differentiation pathway (transdifferentiation). Moreover, mesenchymal stem cells may represent an ideal cell source for treating different diseases. Adult, mononuclear BMCs contain such stem and progenitor cells (≤1%), ego mesodermal progenitor cells, hematopoietic progenitor cells, and endothelial progenitor cells. In several animal infarction models it has been shown that: (1) Bone marrow hemangioblasts contribute to the formation of new vessels: (2) bone marrow hematopoietic stem cells differentiate into cardiomyocytes, endothelium, and smooth muscle cells; (3) BMCs give rise to mesodermal progenitor cells that differentiate to endothelial cells; and (4) endothelial progenitors can transdifferentiate into beating cardlomyocytes. Thus, several different fractions of mononuclear BMCs may contribute to the regeneration of necrotic myocardium and vessels. In order to utilize this large and perhaps heterogeneous regenerative potential, we decided to use all mononuclear cells from the bone marrow aspirate as a whole, rather than a suppopulation. No further expansion was performed because experimental data have revealed a dramatic decline in the homing capacity of in vitro amplified hematopoietic stem or progenitor cells."

Thus, Strauer et al. teach that at the time of the filing of the present application it was unknown which fraction of mononuclear BMCs contribute to regeneration of necrotic myocardium and therefore all mononuclear BMCs were administered instead of enriched fraction of one population.

Itsecu, as discussed above, teaches only that the mononuclear cells can be selected for CD34\* and that these selected and purified cells include at least some cells that include CD133\* markers. Itsecu does not teach further selecting for CD133\* and CD34\* to achieve an enriched population of cells that include at least

75% human CD133\*/CD34\* endothelial progenitor cells let alone using this population in a therapeutic application in combination with a second enriched population of cells consisting essentially of mesenchymal stem cells. There is no discussion in Itsecu that a subpopulation of EPCs, comprising human CD133\*/CD34\* endothelial progenitor cells enriched from umbilical cord blood would be effective in treating ischemic tissue.

Peichev et al. only teach that it is possible to isolate CD34\*CD133\* cells and that CD34\*CD133\* in circulating blood have the capacity to colonize neo-intimal surfaces and that CD34\*CD133\* can form endothelial cells under the right microenvironment. Peichev et al. do not teach administering CD34\*CD133\* cells to a subject for any purpose let alone to treat ischemic tissue or induce the formation of blood vessels. The fact that CD34\*CD133\* endothelial prgenitor cells can migrate along with other CD34\* cells and potentially form endothelial cells does not show that such endothelial cells will treat the ischemic tissue or promote the formation of blood vessels. Further, Peichev et al. provide no teaching to one skilled in the art that an enriched population of CD34\*CD133\* cells comprising at least 75% human CD133\*/CD34\* endothelial progenitor cells can be administered to a subject and would provide any potential effect on ischemic tissue alone or in combination with a second population of mesenchymal stem cells.

Moreover, one of ordinary skill in art have not found it predictable and/or had a reasonable expectation of success that ischemic tissue could be treated by an enriched population of CD34\*CD133\* cells comprising at least 75% human CD133\*/CD34\* endothelial progenitor cells enriched from umbilical cord blood. As

discussed above, Strauer et al. teach using a mixed population mononuclear BMCs as several different fractions of mononuclear BMCs may contribute to regeneration myocardial tissue. Itesecu teaches selecting for CD34<sup>+</sup> cells and administering these cells in combination with a chemokine but does not teach an enriched population of CD34<sup>+</sup>CD133<sup>+</sup> cells comprising at least 75% human CD133<sup>+</sup>/CD34<sup>+</sup> endothelial would have an effect. Peichev et al. show only that LVAD surfaces are colonized with CD34<sup>+</sup> cell and that of these CD34<sup>+</sup> cells, 4% on neo-intimal surfaces are CD133<sup>+</sup> cell.

Thus, at the time of filing present application, it was not known that administration of an enriched population of CD34\*CD133\* cells comprising at least 75% human CD133\*/CD34\* endothelial cells to a subject would have any effect on treating ischemic tissue or inducing the formation of blood vessels in the ischemic tissue. One skilled in the art could not infer, find it predictable, and/or have a reasonable expectation of success that administering to a subject a therapeutically effective amount of a first enriched population of cells comprising at least 75% human CD133\*/CD34\* endothelial progenitor cells and a second enriched population of cells consisting essentially of human mesenchymal stem cells would treat the ischemic tissue and/or induce the formation of blood vessels in the ischemic tissue. It has been held that a claim is not obvious where the improvement of the prior art is more than a predictable use of prior art elements according to their known function or use. In re Kubin, 561 F.3d 1351, 1359 (Fed Cir. 2009). Therefore, claims 1 and 54 are not obvious in view of Strauer et al., Shake et al., Ueno et al., Kawamoto et al., Itescu et al., and Peichev et al.

## iv. The invention recited in claims 1 and 57 exhibits unexpected results.

Assuming arguendo, that claims 1 and 57 were obvious in view of Strauer et al., Shake et al., Ueno et al., Kawamoto et al., Itescu et al., and Peichev et al. claims 1 and 57 would still be patentable over Strauer et al., Shake et al., Ueno et al., Kawamoto et al., Itescu et al., and Peichev et al. because the subject matter of claims 1 and 57 exhibit unexpected results.

It is well settled that one may rebut a prima facie case of obviousness based on unexpected results by demonstrating that the claimed inventions exhibits some superior property or advantage that a person of ordinary skilled in the art would have found surprising or unexpected. *P&G v. Teva Pharmaceuticals*, 566 F.3d 989, 999 (Fed. Cir. 2009); *citing In re Soni*, 54 F.3d 746, 750 (Fed. Cir. 1995).

As noted above, attached herewith is a declaration under 37 CFR 1.132 from Dr. Mary Laughlin, an inventor of the subject patent application. The declaration states that Dr Laughlin performed a series of experiments to determine whether stromal cells added to umbilical cord blood (UCB)-derived endothelial progenitor cells (EPCs) would augment neovascularization *in vivo* in a mouse hindlimb ischemia model. Initial results of these experiments are shown in Example 11 of the application. In these experiments human mesenchymal stem cells (hMSCs) were isolated and culture expanded from bone marrow aspirates as described in Example 6, and CD133<sup>+</sup> endothelial precursor cells were isolated and cultured expanded from UCB as described in Example 3 and Example 4. 1x10<sup>6</sup> CD133<sup>+</sup> cells and 1x10<sup>6</sup> hMSC were co-injected intracardially into mice that had undergone hind-limb femoral artery ligation by the method described in Example 2. Blood flow was measured by

laser Doppler flowmeter over time, and the results, which are illustrated in FIG. 17, are expressed as the ratio between the blood flow in the injured and the uninjured leg over time. The results show increased blood flow in the mouse receiving both CD133\* cells and hMSCs at day 7 after surgery compared with mice infused with CD133\* cells or hMSCs alone. This result suggests that improved blood flow was achieved at an earlier time point (day 7) after co-infusion of hMSCs with CD133\* cells compared to infusion with CD133\* cells or hMSCs alone.

Dr. Laughlin further notes that additional experiments conducted in her laboratory tested the effectiveness human bone marrow (BM)-derived mesenchymal stem cells (MSCs) injected alone and in combination with UCB-derived CD133+ HSCs in treating an in vivo mouse hindlimb femoral ligation model. Significantly enhanced blood flow and histologic evidence of angiogenesis was noted in an in vivo non-obese diabetic/severe combined immunodeficiency disease (NOD/SCID) mouse hindlimb femoral ligation model (See Attachment B). Femoral ligation and resection was performed and study animals were randomized to one of three treatment groups. Group 1, control, was treated with injection of media (0.02 ml). Group 2 animals received third passage human MSC (1x10<sup>6</sup> in 0.02 ml). Group 3 animals received both UCB CD133+ HSCs and MSCs at an equivalent total cell dose  $(0.5x10^6 + 0.5x10^6 \text{ in } 0.02 \text{ ml}; \text{ total combined human cell dose } 1x10^6 \text{ in } 0.04 \text{ ml}).$ The animals survived for 6 weeks. There were significant differences in the Doppler blood flow ratio measured at day 42 among the three conditions. Pair-wise comparison revealed significantly higher blood flow measured in animals injected with both MSCs and UCB 133+ HSCs compared with those animals treated with

MSCs alone (p<0.05). Taken together, these experiments show the synergy of UCB 133+ HSCs and MSCs in mediating murine angiogenesis responses to ischemic vessel injury

Dr. Laughlin also notes experiments conducted in her laboratory that compared the effectiveness of umbilical cord blood (UCB) derived selected CD133+ cell to BM CD133<sup>+</sup> cells, non-selected bone marrow-derived mononuclear cells (BM MNCs), and non-selected UCB MNCs at mediating neovascularization in vivo in a non-obese diabetic/severe combined immunodeficiency disease (NOD/SCID) mouse femoral ligation vascular injury model. As shown in the attached publication, Cytotherapy, 2010: 12: 67-78, which is discussed above, she found: (i) CD133<sup>+</sup> cells selected from UCB exhibited enhanced vasculogenic functionality compared with BM CD133+ cells, BM MNCs, and UCB MNCs in response to ischemia; (ii) blood flow in NOD/SCID mice 4 weeks after femoral ligation was significantly higher in animals injected with UCB-derived CD133+cells compared to BM CD133+ cells, UCB MNCs, and BM MNCs and control at 28 days despite administration of a lower cell dose (0.5 X 10<sup>6</sup> CD133<sup>+</sup> versus 1.0 X 10<sup>6</sup> MNC), highlighting the benefit of using a selected cell population instead of heterogeneous MNCs or BM CD133\* cells; and (iii) examination of human cell engraftment in the marrow was highest in NOD/SCID mice receiving UCB-derived CD133+ cells compared to NOD/SCID receiving BM CD133<sup>+</sup> cells, UCB MNCs, and BM MNCs.

Thus, the administration of an enriched population of UCB CD133<sup>+</sup> cells to ischemic provides improved or enhanced vasculogenesis in the ischemic tissue compared to the administration of an enriched population of CD133<sup>+</sup> bone marrow

cells, a heterogenous population of BM MNCs, and a heterogenous population of UCB MNCs. Moreover, Example 11 and the attached redacted grant demonstrate that administering an enriched population of UCB CD133\* cells in combination with an enriched population of human mesenchymal can synergistically improve blood flow at an earlier time and promote enhanced vasculogenesis in ischemic tissue in comparison to the administration of UCB CD133\* cells alone and MSCs alone. Therefore, administering to a subject a therapeutically effective amount of a first enriched population of cells comprising at least 75% human CD133+/CD34+ endothelial progenitor cells enriched from umbilical cord blood and a second enriched population of cells consisting essentially of human mesenchymal stem cells provided enhanced vasculogenesis in the ischemic tissue compared to UCB derived CD133+ cells alone, MSCs alone, BM CD133+ cells, a non-selected population of BM MNCs, and a non-selected population of UCB MNCs. Accordingly, the methods recited in claims 1 and 57 exhibit unexpected results compared to the closest prior art and withdrawal of the rejection of claims 1 and 57 is respectfully requested.

Claims 2, 4, 10-12, 21, 23-36, 40-43, 50-53, 56 and 67-69 depend directly or indirectly from claim 1 and are therefore allowable because of the aforementioned deficiencies in the rejection with respect to claim 1 and because of the specific limitations recited in claims 2, 4, 10-12, 21, 23-36, 40-43, 50-53, 56 and 67-69.

Claim 54 includes similar limitations to claim 1 and therefore is allowable because of the aforementioned deficiencies in the rejection with respect to claim 1 and because of the specific limitations recited in claim 57.

Claim 55 depends directly or indirectly from claim 54 and is therefore allowable because of the aforementioned deficiencies in the rejection with respect to claim 54 and because of the specific limitations recited in claim 55.

In view of the foregoing, it is respectfully submitted that the present application is in a condition of allowance and allowance of the present application is respectfully requested.

Please charge any deficiency or credit any overpayment in the fees for this matter to our Deposit Account No. 20-0090.

Respectfully submitted.
